Abstract

Corona-virus pandemic has become a major health problem worldwide. It evokes mental health disorders affecting population globally, especially the pregnant women and associated with adverse maternal and fetal outcomes. Therefore, we aimed to assess anxiety and depression among pregnant women during this lethal outbreak of corona-virus. We conducted a cross-sectional study at Hamdard University Hospital, Karachi from October 2020 to February 2021. A total of 120 pregnant women were included in this study. Psychological Impact was assessed using questions from DSM-5 Self-Rated Level 1 Cross-Cutting Symptom Measure for Adults and data was analysed using the software IBM SPSS Statistics 26. We found that more than half (67.5%) of pregnant women had developed mental health disorders during this pandemic and there is a need to reform policies for the care and counselling of pregnant women as they are particularly susceptible.

Keywords: Corona-virus pandemic, mental health problem, depression, pregnant women.

INTRODUCTION

Coronavirus, or Covid-19, is highly infectious and spreads through respiratory droplets and person to person contact. It was first identified in Wuhan, China in December 2019, and because of the rapid spread of the virus, it was declared a pandemic by the World Health Organization on 11th March 2020. The symptoms include fever, cough, and loss of taste and smell which begin to appear around 14 days after exposure [1]. The first case reached Pakistan on 26th February 2020. Due to the uncertainty and the lack of treatment options, as well as lockdowns, social isolation, and the drastic change in daily life, Covid-19 has had major effects on the mental health of individuals.

One of the most affected group is pregnant women. There is little information available on how covid-19 affects pregnancy and childbirth. Some of the fears of pregnant women include potential vertical transmission and associated fetal abnormalities, the effects of the virus on the long-term health of the mother and child, as well as access to proper healthcare during lockdown restrictions.

Depression or anxiety during pregnancy is associated with adverse outcomes, especially preterm birth, and low birth weight of the baby [2]. Healthcare professionals need to take into account the mental health of their patients in order to make proper management plans during their pregnancy. In times of a global health crisis, knowledge about maternal mental health is increasingly important to influence the attitude of healthcare providers and public health strategy.

Most studies conducted on Covid-19 focus on decreasing mortality and managing the illness, however, comprehensive research on the psychological effects of the global pandemic is limited, especially when it comes to pregnant women. A review conducted by Kotlar et al., in January 2021 found that psychological distress among pregnant women during Covid-19 was likely, but more evidence was needed.
Therefore, there was a need to carry out a study assessing anxiety and depression in pregnant women during the Covid-19 pandemic.

Study Design
This was a cross-sectional study conducted at Hamdard University Hospital, Karachi from October 2020 to December 2020. Hamdard University Hospital is a tertiary care hospital that sees patients from all over Pakistan. Pregnant women visiting the gynae outpatient department, and women who had recently delivered in the gynae ward (in the past 15 days) were included in the study and asked to fill out a questionnaire. Patients who had depression or any other mental health issue were excluded from the study. Ethical approval was taken from the institutional review board before administering the questionnaire.

Questionnaire
The questionnaire asked about the patient’s age, gestational age, level of education and occupation. Written consent was taken from all patients who participated in the study. Psychological Impact was assessed using questions from DSM-5 Self-Rated Level 1 Cross-Cutting Symptom Measure for Adults and measured using a Likert Scale with scores from 0 to 4, with 0 indicating none and 4 indicating Severe. Three domains: Depression, Anxiety and Sleep Problems were used to assess the psychological impact of the Covid-19 pandemic in the pregnant population. Patients were also asked additional questions about their knowledge about Covid-19 and their habits during the pandemic. Questions included if they checked social media for information about Covid-19, if they missed any antenatal appointments because of fear of getting the virus, and if they feared pregnant women were at a risk of miscarriage, or early labour upon contracting the virus. Questions also asked about their knowledge of Covid-19 pertaining to birth and the baby, such as if they thought a caesarean section was a safer option during the pandemic, and if infected mothers should breastfeed their babies. Questionnaires were handed out in both English and Urdu.

Statistical Analysis
The data was analysed using the software IBM SPSS Statistics 26. Frequency and percentage were used to compare the data. Variables of interest were rates of depression, sleep problems, and changes in appetite, as well as demographic information such as level of education, occupation, and the age of the patients. Variables such as checking social media for information, and missed antenatal appointments. Data relating to perception about breastfeeding while infected, risk of transmission, fears of miscarriage or early labour was also studied.

RESULTS
A total of 120 patients filled out the questionnaire. Out of the total, 86 (71.7%) of the patients were less than 30 years, 29 (24.2%) were between 31 and 35 years old, and only 5 (4.2%) were older than 35 years.29 (24.2%) had Covid-19 testing done before. Out of the total participants, almost half i.e., 59 (49.2%) said they had missed clinical appointments for fear of contracting Covid-19. More than half (67.5%) said Covid-19 had impacted their mental health. The summary of the psychological impact is given in Table 1. 77 (64.2%) said the pandemic made them depressed or anxious. Lack of appetite and disturbance in sleep patterns was found as well (51.7% and 53.3% respectively) Table 2. 86 (71.7%) reported checking for news about the pandemic on social media. Table 3. 66 (55%) of the women believed there was a risk of transmission to the baby should they be infected, however almost half of the women (42.5%) said it was safe for infected mothers to breastfeed. 55 (45.8%) women thought pregnant women were more likely to miscarry or go into labour early if they contracted Covid-19.

DISCUSSION

Our study found that the mental health of pregnant women was adversely affected due to the Covid-19 pandemic and ensuring lockdown. This is in line with previous studies done in other places [4, 5]. Our study showed a higher percentage of anxiety and depression in Pakistani pregnant women compared to a study carried out by Shahid et al., in the early months of the pandemic [6]. This might suggest a trend in increased rates of mental health issues as the pandemic goes on. However, the sample sizes of these studies differ so they cannot be accurately compared.

Studies done in Pakistan assessing the mental health of women found that marital status, having children [7], and living in a large household [8] were factors associated with increased levels of anxiety and depression. Similar to these studies, our data also found a higher number of housewives, with only 11 women saying they were working and only 16 women saying they had education up to a tertiary (college) level (Table 2). Sut et al., found the risk of depression in women with less than nine years of education was 2.76 times higher [5]. In the context of Pakistan, this could be due to less awareness of mental health and fewer resources available to women with lower education levels, a decreased ability to self-advocate, and more compliance with traditional norms, which might not be promoting conversations about mental health, especially in the face of a new, widespread crisis like the Covid-19 pandemic. It should be noted that 32 out of the 120 women choose not to answer questions about their education and occupation.

A study by Xue Yang et al., suggests that pregnant women with less social support, pregnancy experience or access to healthcare experienced more mental health issues [9]. A randomized controlled trial
done on Pakistani women comparing a six-week social
support program to a single mental health awareness
session found significant change in resilience in the six-
week intervention group. The study also reported that
even the control group attending a single session
reported a slight improvement in resilience [10].
Although it is not realistic for a low-income country
like Pakistan to incorporate large scale mental health
awareness programs as part of the policy against Covid-
19, doctors and health care workers who come in
contact with patients, especially pregnant women who
are at an increased risk of mental health issues, should
be trained to counsel them effectively and point them
towards useful resources to improve mental health.

Almost half of the patients reported missing a
clinical appointment due to fear of contracting the virus.
This is slightly concerning and highlights the need for
alternative ways for doctors to follow-up on their
patients, such as online consultations, during times of
crisis. However, a tertiary care hospital like Hamdard
receives patients from all over Karachi and Baluchistan,
and even Afghanistan and Iran. Not all of these patients
have access to proper internet services, or an
understanding of the language (usually English) needed
to work out how to access online clinics.

We were able to compare the number of
women who used social media for information about
Covid-19 and those who said the pandemic had an
effect on their mental health. Our study found a link
between the use of social media for news and poor
mental health (Table 3). The results are in accordance
with a study by Gao et al., which found an association
between social media use and mental health problems
[11]. Social media and messaging applications have had
a major impact on people’s lives during this pandemic,
especially as a source of information. This has led to the
spread of misleading and unscientific claims being read
and shared amongst the population. Constant exposure
to unclear, alarming news serves to increase anxiety
levels in people. Misinformation creates barriers in the
way of healthcare and only contributes to distrust
between the healthcare system and the patient. As we
wait for the Covid-19 vaccine to be made available to
the general population, there is an urgent need for a
public awareness campaign to spread accurate,
validated information about the benefits of the Covid
vaccine. Reluctance around vaccines is a problem in
Pakistan, such as in the case of Polio [12].

Multiple studies from around the world have
been done showing that one of the biggest concerns of
pregnant women is vertical transmission of Covid-19
[13], despite low rates (3.2%) of transmission being
reported in the third trimester [14]. However, a meta-
analysis by Dubey et al., found that adverse outcomes
in pregnancy such as caesarean sections, preterm births,
low birth weight or other adverse outcomes were
associated with women infected with Covid-19 [15].

Our study found that Pakistani pregnant women had
some information about pregnant women being more at
risk for these outcomes.

However, despite guidelines stating that it is
safe for Covid-Positive women to breastfeed their baby
with proper precautions [16], 69 (57.5%) of the
Pakistani pregnant women thought it was unsafe. The
Centers for Disease Control and Prevention (CDC) has
listed precautions for pregnant women which include
social distancing, disinfecting surfaces, proper hand
washing before handling the baby, and wearing a mask
while breastfeeding if the mother is Covid-Positive
[17]. Pregnant or nursing women should be counselled
about these precautions, whether they are suspected of
being exposed to the coronavirus or not.

The limitations of these studies include small
sample size and a single centre design. The lack of a
control population (i.e., non-pregnant women) meant
that the levels of anxiety and depression could not be
compared.

CONCLUSION

Our study found that pregnant women did
experience increased levels of anxiety and depression.
They were found to have some level of knowledge
about the effects of coronavirus; however, doctors still
need to provide proper guidance about the special
precautions patients need to take during pregnancy and
the nursing period. There is a need to reform policies
for the care and counselling of pregnant women when it
comes to their mental health, as they are particularly
susceptible. These policies need to be made not just for
the current pandemic, but for all future global or
national crises.
