Abstract

This study was done to estimate the serum uric acid level pre and post dialysis. To do this 50 patients with chronic renal failure and 50 apparently health individual as control group were involved. Uric acid level was determined for all patients and control group and the result was analyzed using spss package. The mean of serum uric acid pre dialysis is significantly raised compare with that of the control group (9.4±2.2 versus 3.7±0.8). The mean of uric acid post dialysis is significantly decreased compared with that of before dialysis (9.4±2.2 versus 2.7±1.2) and P.value 0.00. The sex frequency for pt with CRF (43.3% female and 56.7% male). The correlation between duration of disease and Serum uric acid significant negative correlation and the (P.value =0.01 r = - 0.40).

Keywords: Serum Uric Acid, Post Hemodialysis, chronic renal failure.

INTRODUCTION

Chronic kidney disease (CKD) is a type of kidney disease in which there is gradual loss of kidney function over a period of months to years. Initially there are generally no symptoms; later, symptoms may include leg swelling, feeling tired, vomiting, loss of appetite, and confusion [2]. Complications include an increased risk of heart disease, high blood pressure, bone disease, and anemia [1-6].

Causes of chronic kidney disease include diabetes, high blood pressure, glomerulonephritis, and polycystic kidney disease. Risk factors include a family history of chronic kidney disease. Diagnosis is by blood tests to measure the estimated glomerular filtration rate (eGFR), and a urine test to measure albumin [7-11].

Exclusion criteria people whom have gout, hypertension and DM.

Sampling

2.5ml of venous blood collected in plain container immediately centrifuge to separate serum for investigation of uric acid or stored at -21c until used.

METHOD

Estimation of Uric Acid (Enzymatic Method)

Principle: (Uricase PAP method)

Uricase converts uric acid to allantoin and hydrogen peroxide, the hydrogen peroxide formed further reacts with phenolic compound and 4-amino antipyrine by catalytic action of peroxidase to form a red colored quinoneimine dye complex.

Intensity of the color formed is directly proportional to the amount of uric acid present in the sample [8].

RESULTS

This study was carrying out in Khartoum hospital, on patients suffering from chronic renal failure.

DISCUSSION

This study was carried out in Khartoum hospital in Khartoum state (Sudan) to throw some light on renal failure patients by estimation of uric acid level in pre dialysis and post dialysis.

The result of this study showed significantly increased in the mean of uric acid level in patients compared with that of the control group Table 2 and 3.

CONCLUSION

Uric acid level elevated in all renal failure patients, but its level return to normal range after dialysis, so that dialysis was to return some of the parameter change (like uric acid) in patient with renal failure to the normal range.
