Tuberculosis (TB) is a communicable disease that is a major cause of ill health, one of the top 10 causes of death worldwide. Actually, TB is curable disease if the patients adhere and treatment be effective. This study aims to identify factors related to medication adherence among pulmonary TB patients. This study was a systematic literature review by identifying cross-sectional study, published in 2016-2021, in English and Indonesian, and full-text. The electronic database that used was Google Scholar and Science Direct with the keywords “Factors” “Medication” AND “Adherence” “TB Pulmonary”. The results obtained 10 articles that related to medication adherence among pulmonary TB patients. There were five dimensions of factors: therapeutic factors, health system factors, environmental factors, socioeconomic factors, and family support factors. Health workers need to consider these factors so that medication adherence among pulmonary TB patients will increase.

**Keywords:** Factors, Medication, Adherence, TB Pulmonary.

INTRODUCTION

Tuberculosis (TB) is a communicable disease that is a major cause of ill health, one of the top 10 causes of death worldwide and the leading cause of death from a single infectious agent (ranking above HIV/AIDS) [20]. TB is caused by *Mycobacterium tuberculosis* which can be transmitted through the air, for example when cough. Usually, TB will attack the lungs (pulmonary TB), but can also spread or attack organs other than the lungs in the body (extra pulmonary TB). TB can be experienced by men and women at various ages, especially adults.

TB disease is still a challenge in public health in many countries. Based on Global Tuberculosis Report by WHO, 7.1 million people with TB were reported to have been newly diagnosed and notified in 2019, up from 7.0 million in 2018 and a large increase from 6.4 million in 2017 and 5.7–5.8 million annually in the period 2009–2012. The biggest contributors to the global increase were India and Indonesia, the two countries that rank first and second worldwide in terms of estimated incident cases per year [20].

Low adherence increases the risk of poor outcomes, including treatment failure, relapse, and development or amplification of drug resistance. TB patients’ medication adherence should not only be considered as a clinical issue but also a public health problem [7]. Based on the issues above, researcher was interested to identify factors related to medication adherence among pulmonary tuberculosis patients by conducting a literature review from Indonesia and other countries.

**RESEARCH METHODS**

This study was a systematic literature review. In this method, the researcher identifies, collects, summarizes, and analyzes relevant articles to answer research question or hypothesis [15]. In this study, researcher did a literature review about factors related to medication adherence among pulmonary tuberculosis patients. The electronic database that used in this study was Google Scholar and Science Direct. The researcher searched literatures with a cross-sectional study type and used keywords “Factors” “Medication” AND “Adherence” “TB Pulmonary”. Literature search was limited from 2016 to 2021. 3.833 articles were obtained and 10 articles were selected based on criteria and related to medication adherence of pulmonary TB patients (Picture 1).

**RESULT**

From the literature review, it was found that research conducted by Pameswari *et al.* [14] 74.07% of the TB pulmonary patients were in the productive age (15-54 years) and most of them were in low economy. Medication adherence level in some studies showed the level non-adherent. Research conduct by Fitri *et al.* [7] showed that 78.4% respondents were medication non-adherence in pulmonary tuberculosis patients. Du *et al.* [5] divided medication adherence level into: high medication adherence (41.84%), medium medication adherence (32.45%), and low medication adherence (25.71%). Meanwhile, research conduct by Pameswari *et al.* [14] identified as many as 55.56% of respondents were adherent, 33.33% of respondents were quite adherent, and 11.11% of respondents were not adherent.

Several studies revealed the factors that related to medication adherence among TB pulmonary patients. In short, Pameswari *et al.* [14] grouped to five dimensions of factors that related to medication adherence: therapeutic factors, health system factors, environmental factors, socioeconomic factors, and family support factors. On health system factors, Woimo *et al.* [21] showed that factors statistically associated with non-adherence: having poor level of knowledge, absence of health information at every visit, pill burden, distance to Tb clinic beyond 10 km, not decentralizing of DOT service, and cost of medication other than anti-Tb. According to research by Fang *et al.* [6], marital status and annual income were independent influencing factors. It could be the socioeconomic factors.

Research conducted by Yadav *et al.* [22], medication adherence was found associated with co-infection, health worker, and favorable time for taking medicine. Meanwhile, research by Fitri *et al.* [7] showed that knowledge, family support, education level, occupation, and attitude had influence on medication adherence in pulmonary tuberculosis patients (p<0.05). Ulfah *et al.* [17] also stated that family supports related to medication adherence of pulmonary TB patients.

It was almost the same as the research conducted by Tukayo *et al.* [18] that there was significant relationship between knowledge (p = 0.043), attitude (p=0.001), side effect of drugs (p=0.012), access to health services (p = 0.002), attitude of health worker (p = 0, 04), family support (p = 0.014) on medication adherence. However, these results were not in accordance with the research conducted by Dogah *et al.* [4], showed that educational level, having treatment supporter, staff attitude, self-perceived wellness, food availability, being on other medication, and household size were not significantly associated with treatment adherence.

**DISCUSSION**

Medication adherence can be defined as the extent to which a patient’s behavior corresponds with the prescribed medication dosing regime, including time, dosing and interval of medication intake [8]. Non-adherence among pulmonary TB patients is a problem that influenced by several factors. In this literature review, several factors could be identified in five dimensions: therapeutic factors, health system factors, environmental factors, socioeconomic factors, and family support factors. These factors must be concern to...
health workers in order to determine interventions that can be carried out to increase the level medication adherence level among pulmonary TB patients.

**Therapeutic factors**

Therapeutic factors are factors related to treatment, such as types of drugs be taken, their side effects, and the duration of treatment. Tuberculosis (TB) is curable disease if the patients receive effective and uninterrupted anti-TB medication within the recommended time. Based on WHO in the guideline for treatment of drug-susceptible tuberculosis [19], the 6-month rifampicin-based regimen 2HRZE/4HR is recommended in patients with drug-susceptible pulmonary TB. It means, patients will receive 4 types of drugs (isoniazid, rifampicin, pyrazinamide, ethambutol) during intensive phase and be followed to 2 types of drugs (isoniazid, rifampicin) for the next 4 months. After an intensive phase treatment for 2 months with a four-drug regimen the TB patients have to accept the continuation phase lasting more than 4 months according to the WHO recommendation [5]. TB patients could be more likely to show nonadherence in continuation phase because they have improved signs and symptoms of the disease and even might think they are cured; thus, they might be careless in taking medications [11].

**Health system factors**

Health system factors affect to medication adherence among pulmonary TB patients. These factors include: health education, home visit, availability of anti-TB drugs, and quality of drugs, transportation availability and distance to public health center [14]. The role of health workers in providing health service to pulmonary TB patients is very important, especially in providing information about the importance of taking medication regularly and uninterrupted, the rules of taking medication, the symptoms of side effect that may be experienced by patients, listen to patients complain, and provide the solution.

Promoting knowledge through health education can increase adherence to tuberculosis treatment. With adequate knowledge, many patients with tuberculosis will become more compliant and complete treatment [10] Vice versa, the lack of knowledge will increase the rate of non-adherence among pulmonary TB patients. This is in line with research conducted by Woimo et al. [21], showed that factors statistically associated with non-adherence were having poor level of knowledge that was caused by none or lack of information provided by health workers at every visit.

**Environmental factors**

One of the environmental factors that affects medication adherence among pulmonary TB patients is negative stigma about pulmonary TB that spreads in public. The term ‘stigma’ refers to ‘exclusion, rejection, blame, or devaluation resulting from experience or reasonable anticipation of an adverse social judgment’ because of a particular condition [13]. Because of the negative stigma about TB, patients feel ashamed and afraid of being ostracized if the neighbors find out that they have been diagnosed TB. This causes delay in diagnosis, TB patients do not want to receive the treatment, and medication adherence increases. Stigma leads to feelings of shame, tainted identity, increases the stress associated with illness, and contribute to psychological and social morbidity.

**Socioeconomic factors**

From the literature review, it was found that the TB pulmonary non-adherence patients were in the productive age and most of them were in low economy. Although diagnostic examinations and anti-TB drugs are obtained for free, patients need additional costs for food during healing process, transportation cost to the public health center, and other drugs that are not covered by health insurance. About 75% of TB cases arise during people's most productive years between the ages of 15 and 54, while people who are infected by TB are often unproductive and unable to work which affected their family members [3]. This causes medication non-adherence increases.

**Family support factors**

Family support means the existence of comfort, attention, appreciation or to help people with an attitude of accepting the conditions, obtained from individuals and group [12]. The role of family as taking drugs supervisor is very necessary to ensure medication adherence among pulmonary TB patients in the intensive and advanced phase. In the intensive phase, medication adherence is needed to prevent resistance to anti-TB drugs. Meanwhile in advanced phase supervision is needed because this phase lasts longer so that non-adherence is very likely to occur. Patients with frequent medication supervision by family members and patients whose family members often encouraged them mentally were more likely to have a high level of adherence [2].

Theoretically, according to Friedman (1998) family support is divided into four dimensions: emotional support, appraisal, material, and information support [12]. Emotional support is a form of affection given by the family to one family member who suffers from an illness. Emotional support provided by the family to patients will encourage patients to be able to undergo treatment regularly; this is because the support provided is used as a driving force for patients in carrying out a therapy program [1]. Emotional support to patients is needed to increase the self-esteem of pulmonary TB patients because they usually feel ashamed of their disease). Information support can be in the form of giving advice, suggestions, instruction, and providing information to the patients about treatment. Material support provided by family to the patients can be in the form of funds, assistance, and strict...
supervision. Appraisal support is given to the pulmonary TB patients focuses on positive aspect in the form of praise for health progress, always loves, and pays attention to the patient’s condition during illness and accepts patients as they are [16].

**SUMMARY**

From the literature review, factors related to medication adherence among pulmonary TB patients divided into five dimensions: therapeutic factors, health system factors, environmental factors, socioeconomic factors, and family support factors. Health workers need to consider these factors so that medication adherence among pulmonary TB patients will increase.
